# Demographic Profile of India

---

- **Total Population** – 1.2 billion
- **Sex Ratio** – 940/1000
- **Rural Population** – 72.1%
- **Median age** – 25.1 years
- **TFR** – 2.43
- **Total workforce participation** – 39.8% (Census 2011)
- **Education Expenditure** – 3.8% of GDP (2013)
- **Health Expenditure** – 4.7 % of GDP (2013)

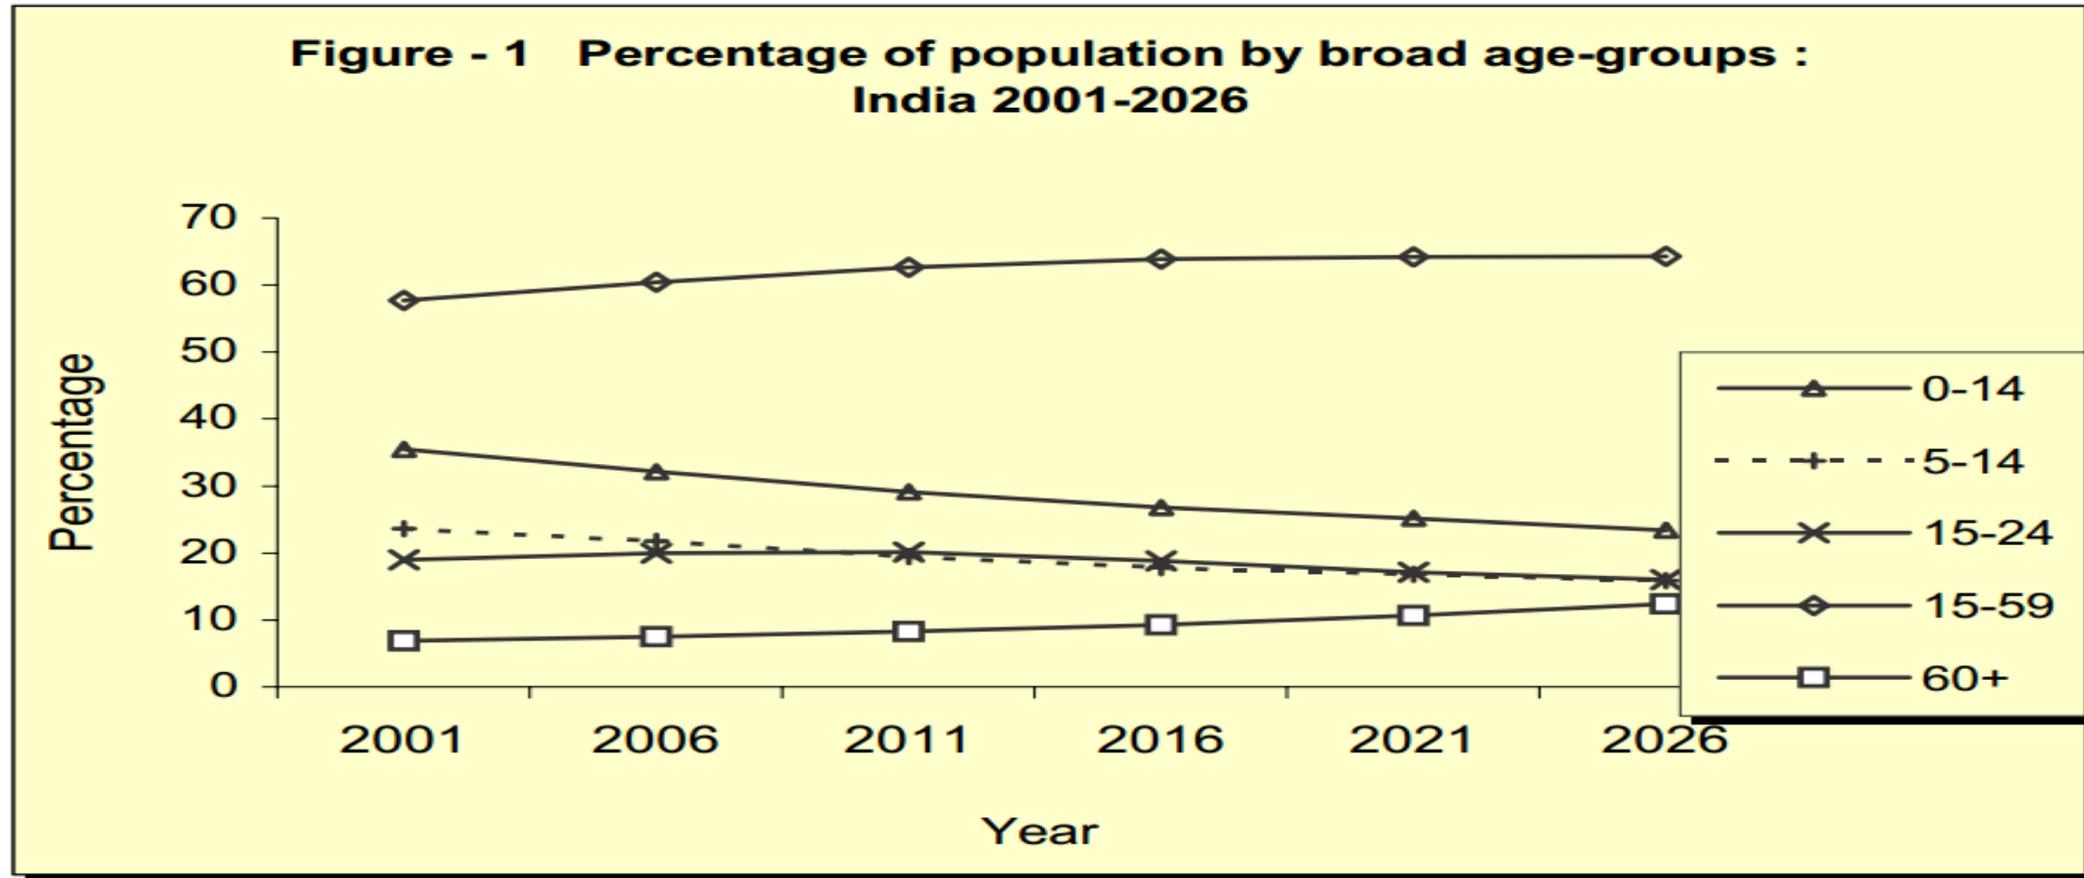

# Introduction

- The world's population is changing from high fertility and mortality to low fertility and mortality as part of the demographic transition
- During this transition period, the economy goes through the window of opportunity period or demographic bonus. In the initial stage, which is called the first demographic dividend, the working-age population is large, and in later stages the accumulation of wealth creates the second demographic dividend
- According to the SRS Report, the share of India's youth population is about 64.4 percent of the total population

# Economic Lifecycle

---

- The economic lifecycle is a universal feature of all contemporary societies. People experience a long period of dependency at the beginning and the end of their lives.
- Initially children are too young to engage in productive activities and they are still acquiring the skills and knowledge needed to be productive.
- Old-age dependency occurs because of lack of money after retirement and higher prevalence of health-related problems, which prevents old people from engaging in economically productive activities.
- So, children and the elderly generally either have insufficient income or no income and face a lifecycle deficit, i.e., excess consumption over income.
- India is a developing nation and enjoying the first demographic dividend, and ageing is taking place slowly. In this position, the children are facing lifecycle deficit in larger proportion compared to the elderly.

# Income and Consumption Curve

# Rationale of the Study

- Only a handful of studies explores the lifecycle deficits in the context of India.
- By reviewing the existing literature, the study have observed that there is a paucity of studies regarding the lifecycle deficit in India.
- Keeping in mind India's demographic profile, the study also explores the LCD in terms of gender, residence and social groups.

## Gender

- Indian society mostly follows the patriarchal system, where girls and women suffer discrimination throughout their lifecycle on both the supply and demand side.
- According to the 2011 census, the workforce participation rate for females is 25.51%, compared with 53.26% for males.
- Women and men may also differs as a providers of care to future generations. In particular, women spend considerable time in rearing their children, doing household chores and providing critical support to the elderly.
- Woman suffer with lower education and skill development along with multidimensional vulnerability.

# Rationale of the study (continued)

---

## **Place of residence**

- According to India's demographic profile, more than two-thirds of the population live in rural areas.
- There is a huge gap between rural and urban India in terms of accessibility, affordability and availability of facility, technology, living conditions, economy, awareness, education, health care, nutrition and other basic needs.
- The rural economy is basically a low-income subsistence economy.

## **Social group discrimination**

- India is characterized by deeply entrenched social hierarchies, defined by caste and religion, which effectively reduces the opportunity for lower-status groups to gain access to social services and limits their participation in the labour market.
- Intergenerational social mobility is limited in low-status population groups categories.
- After independence, affirmative action has favored low-status groups in terms of education and employment to bring them into in the mainstream.

# Objectives

---

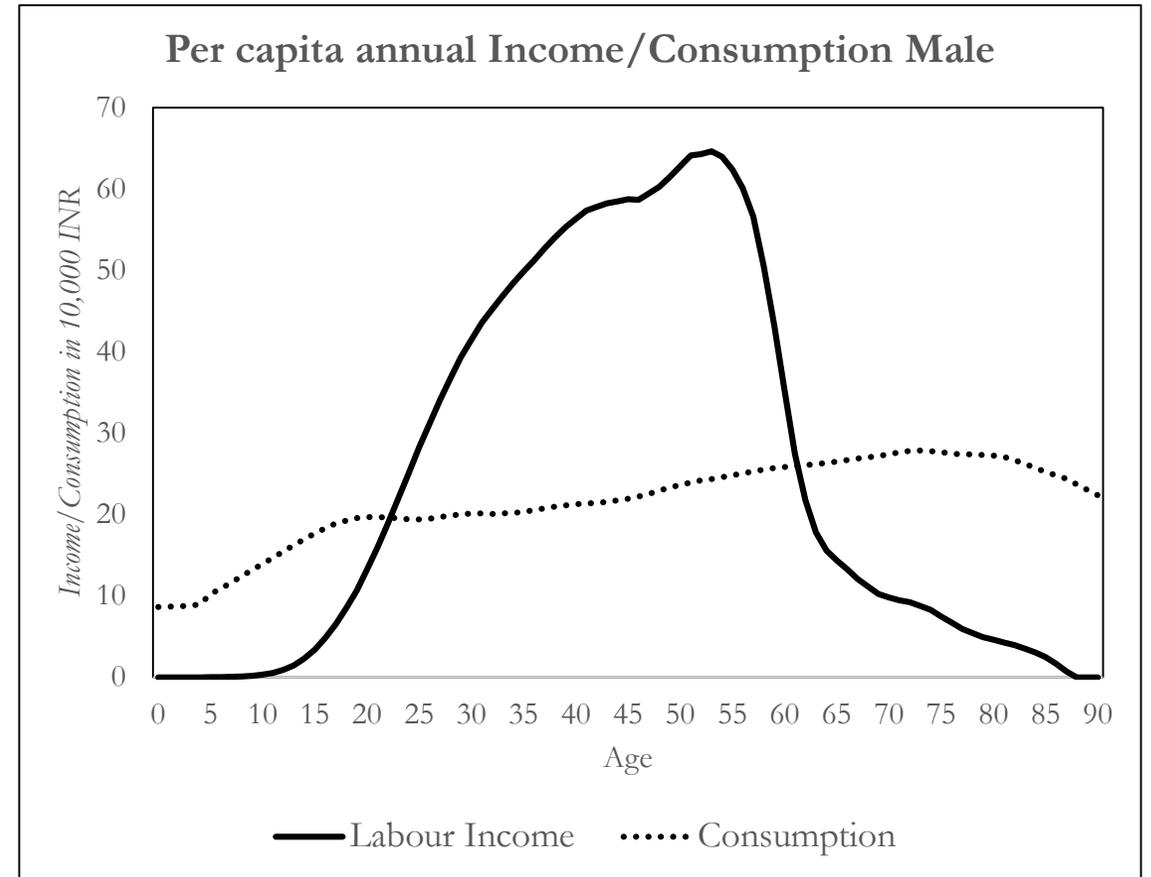

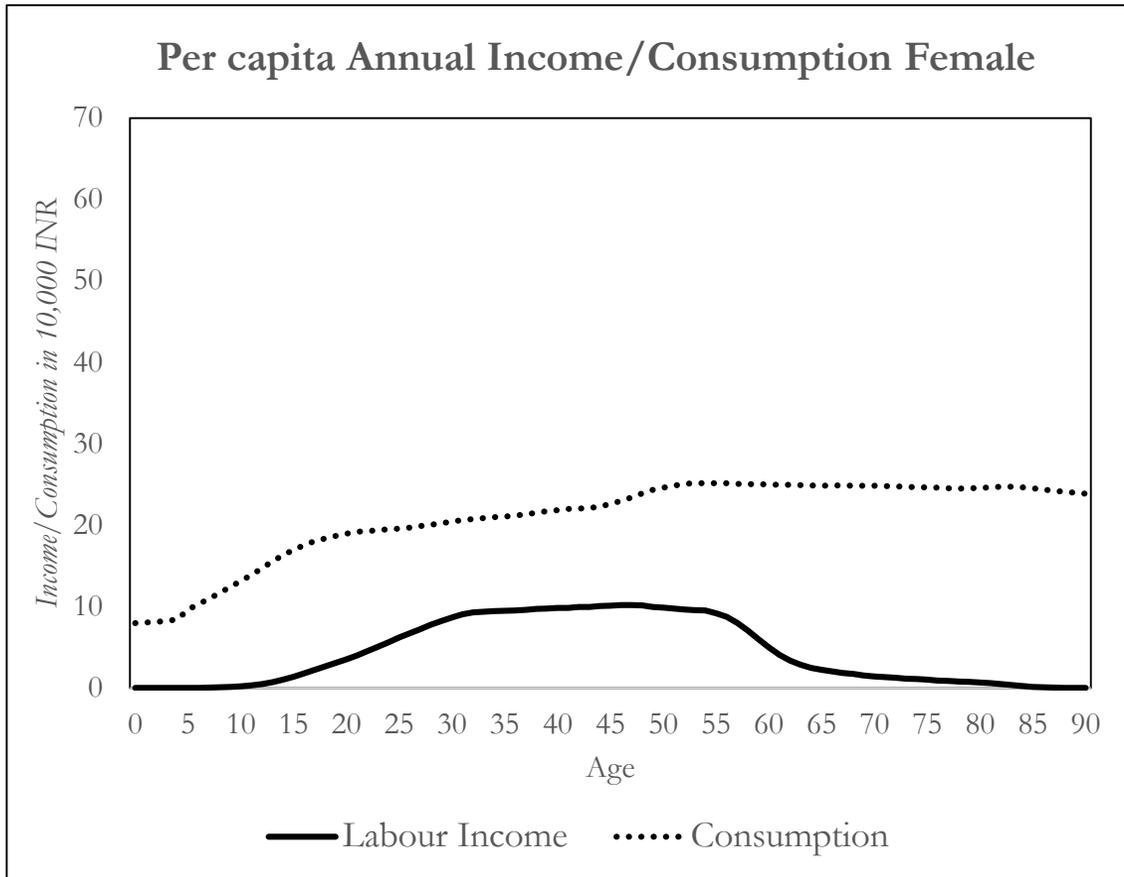

- To study the age patterns of total labour income by gender, residence and socio-economic group during the period of 2004-2005.
- To assess the age pattern of public and private consumptions by gender, residence and socio-economic groups during the period of 2004-2005.
- To estimate the lifecycle deficit by age, gender, residence and socio-economic group during the period of 2004-2005.

# Data sources

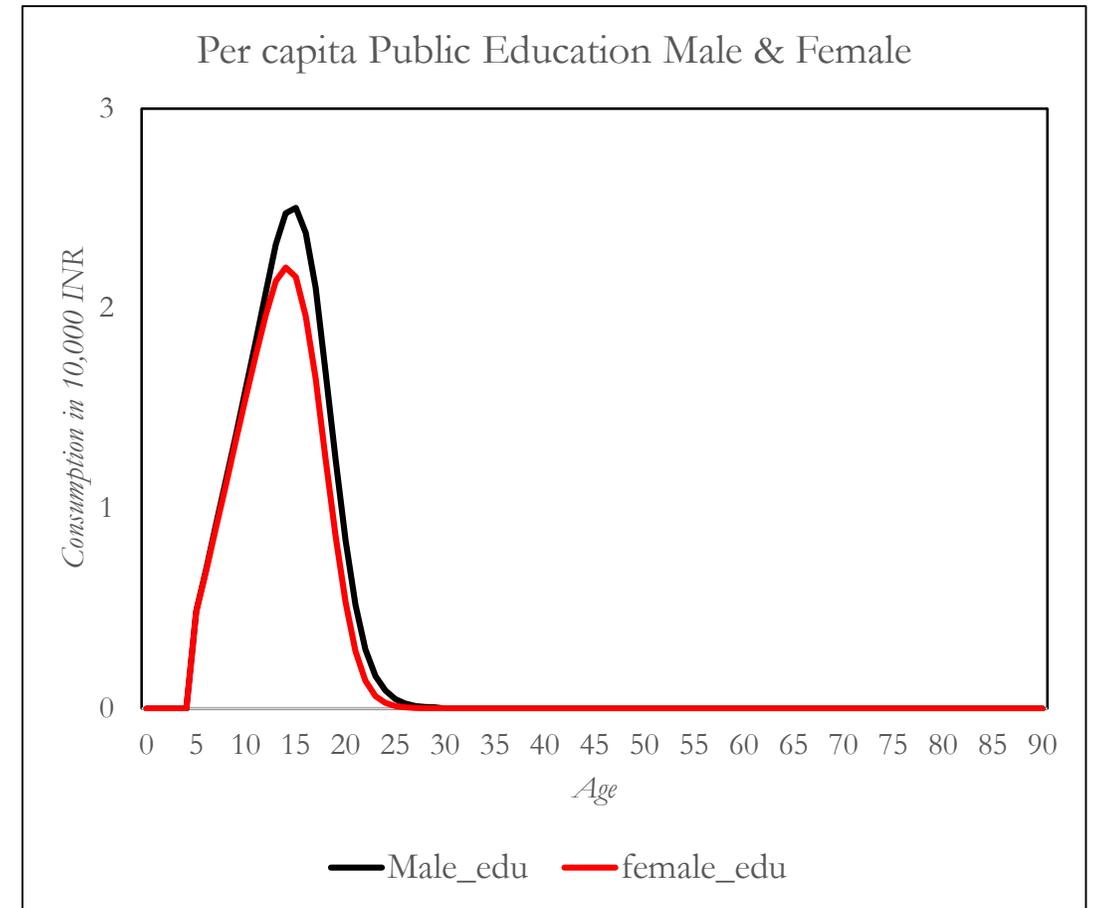

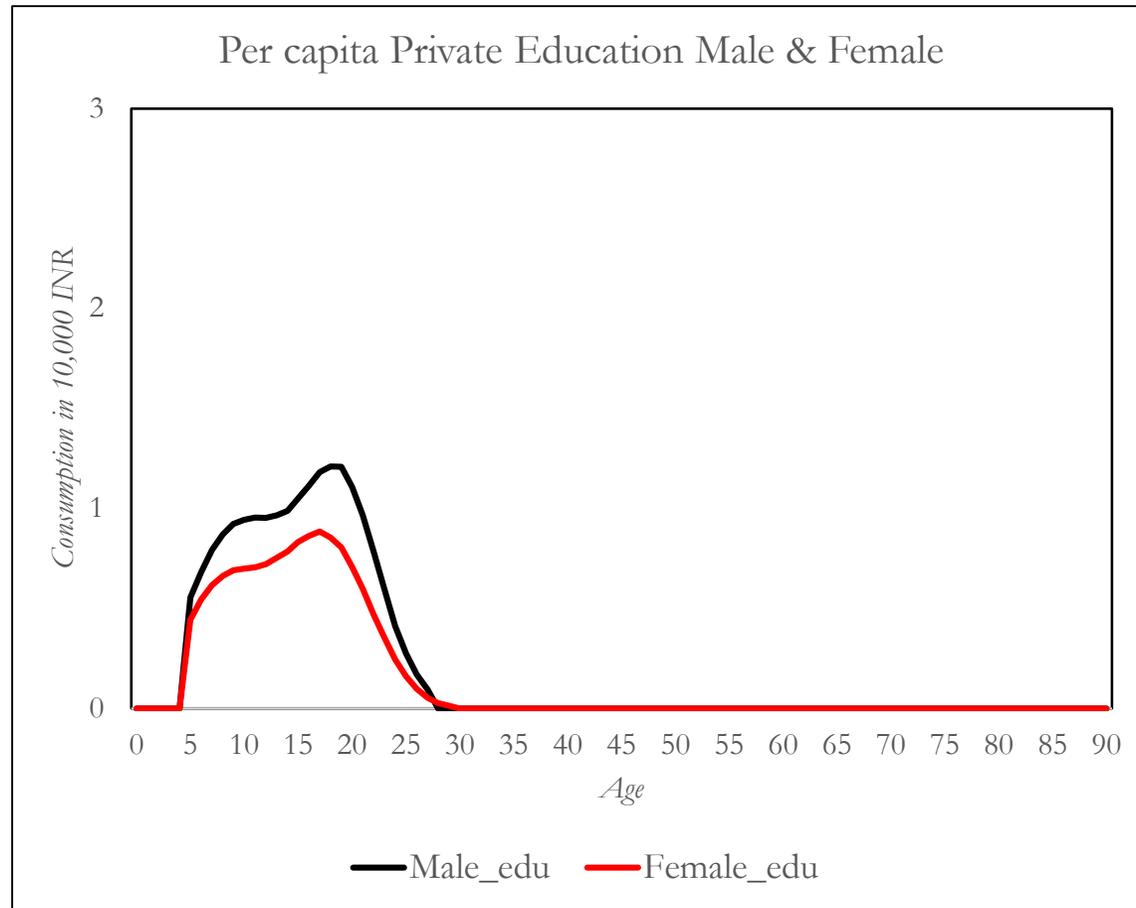

---

- Population age groups based on census data
- Macro data based on National Accounts Statistics (Government of India 2008) for the financial year 2004-2005
- The India Human Development Survey (IHDS I) (Desai and others, 2008) conducted during 2004-05 is the source of micro data, financial and expenditure data
- The IHDS is a nationally representative survey covering 200,000 individuals from more than 41,000 households spread over 1,503 villages and 971 urban localities

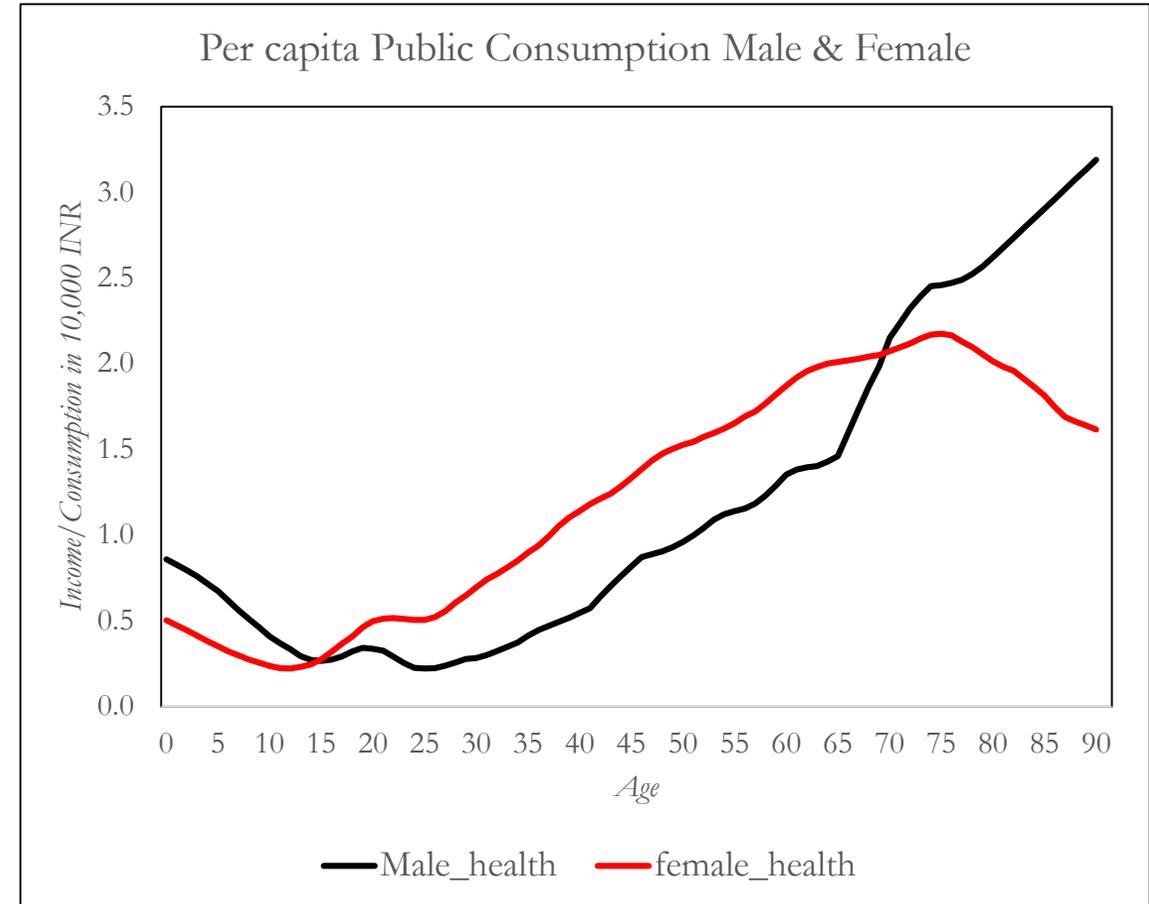

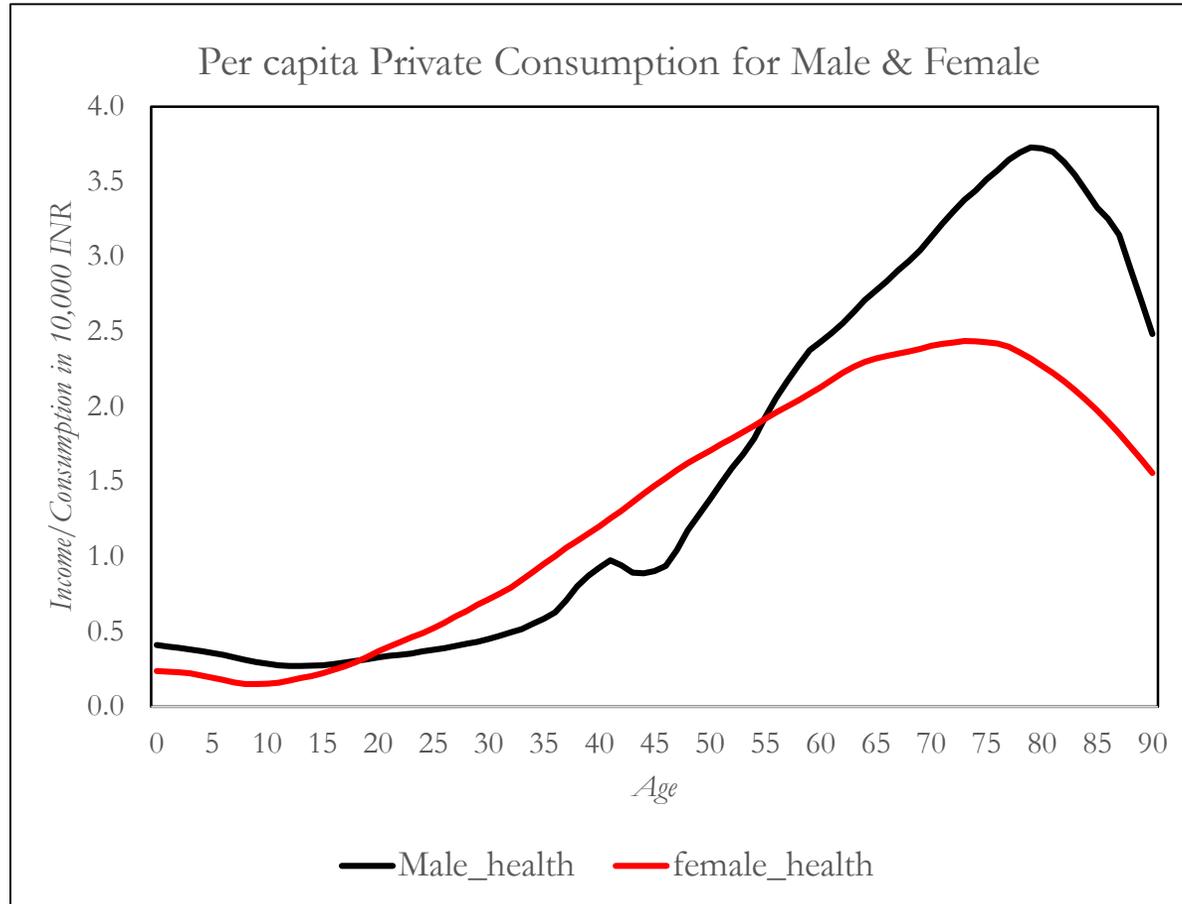

# Gender differential in consumption and income

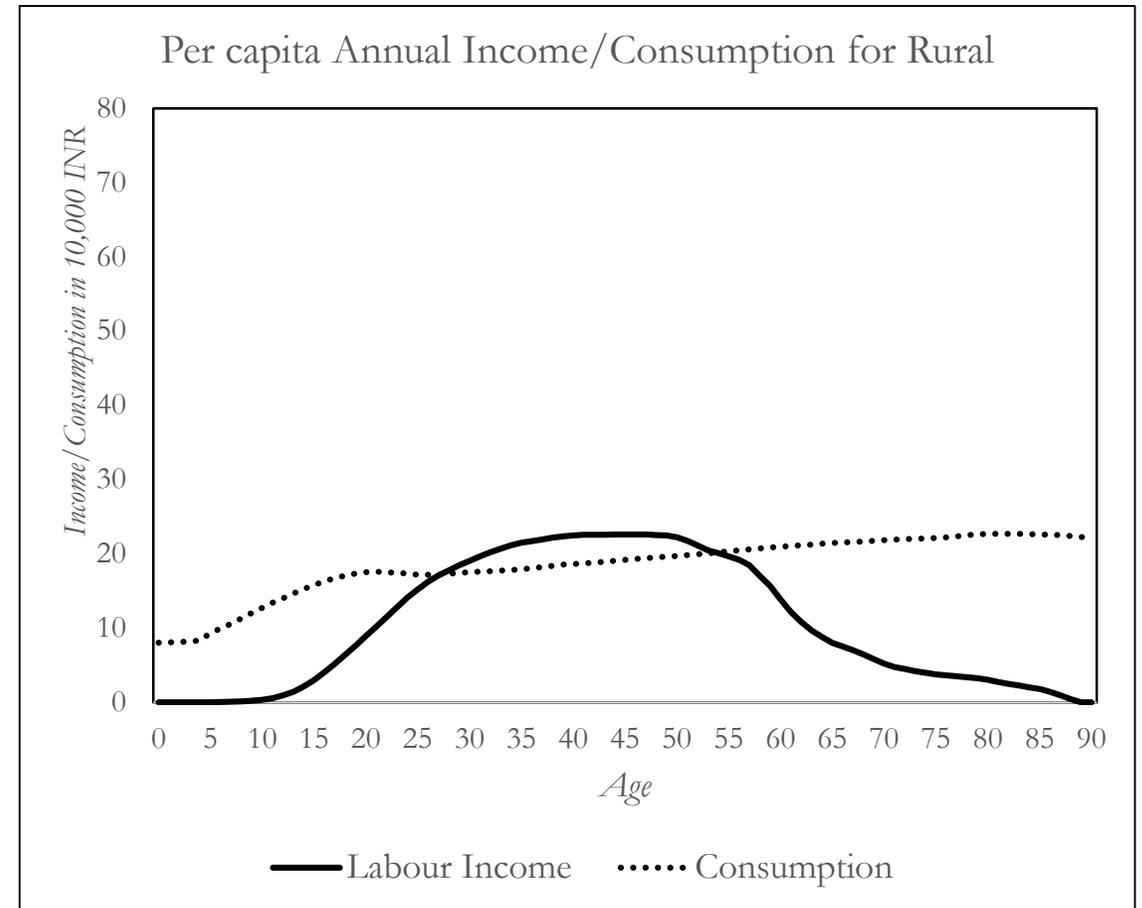

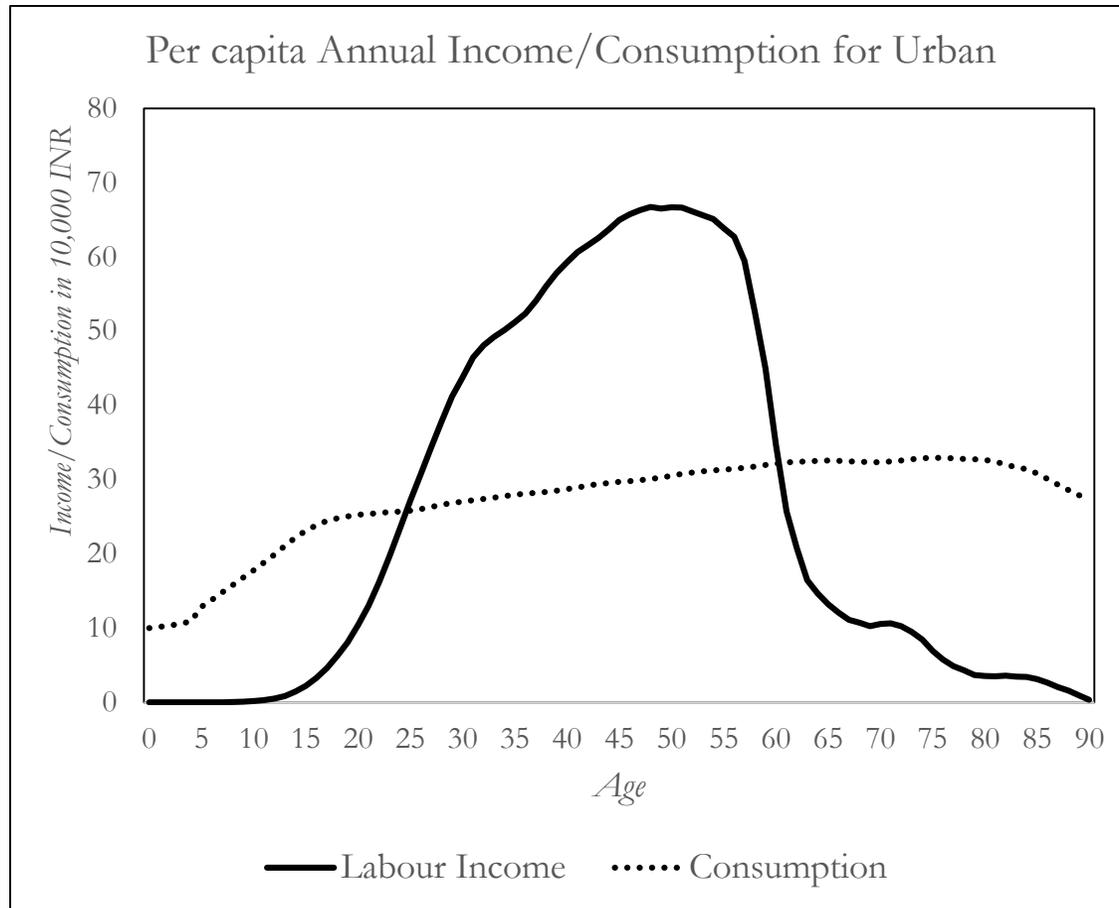

# Gender differential in education consumption

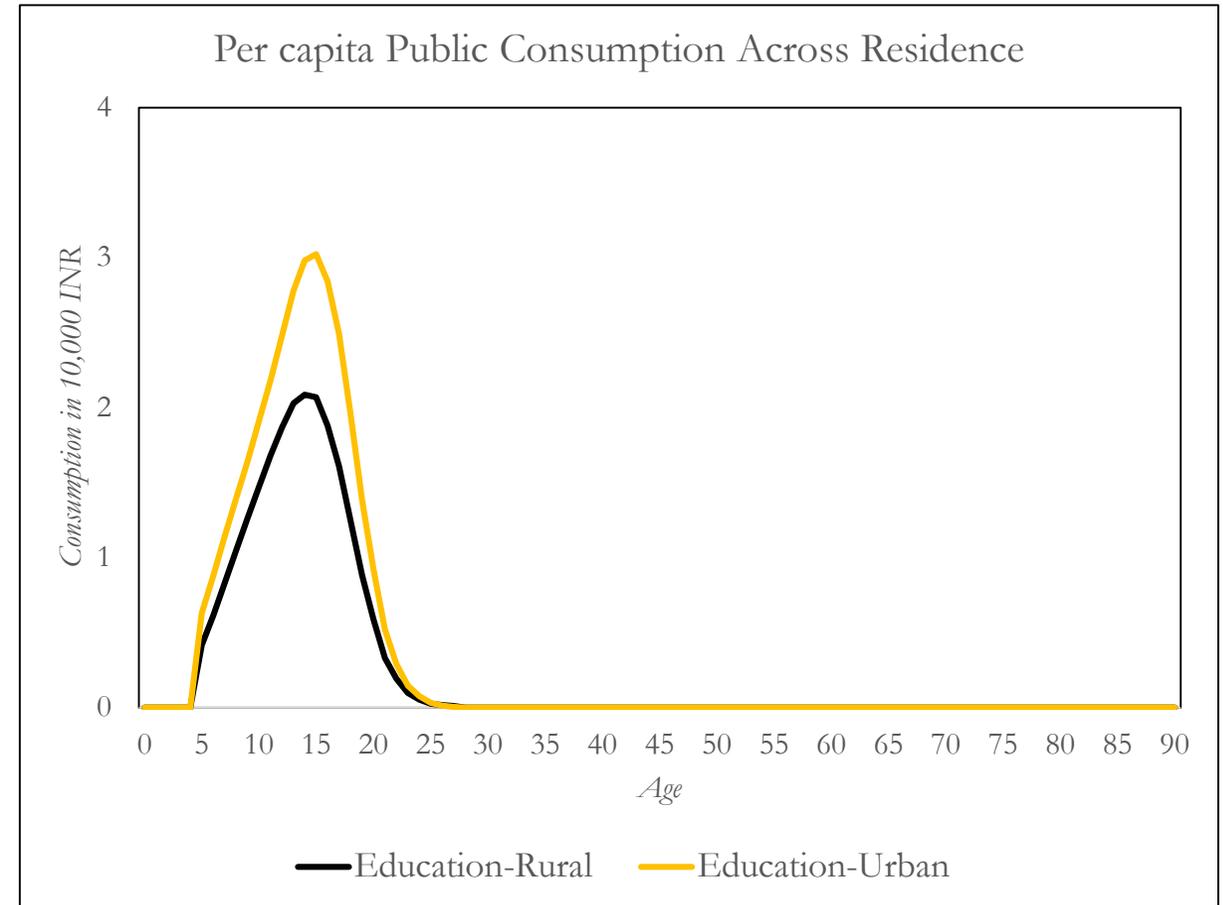

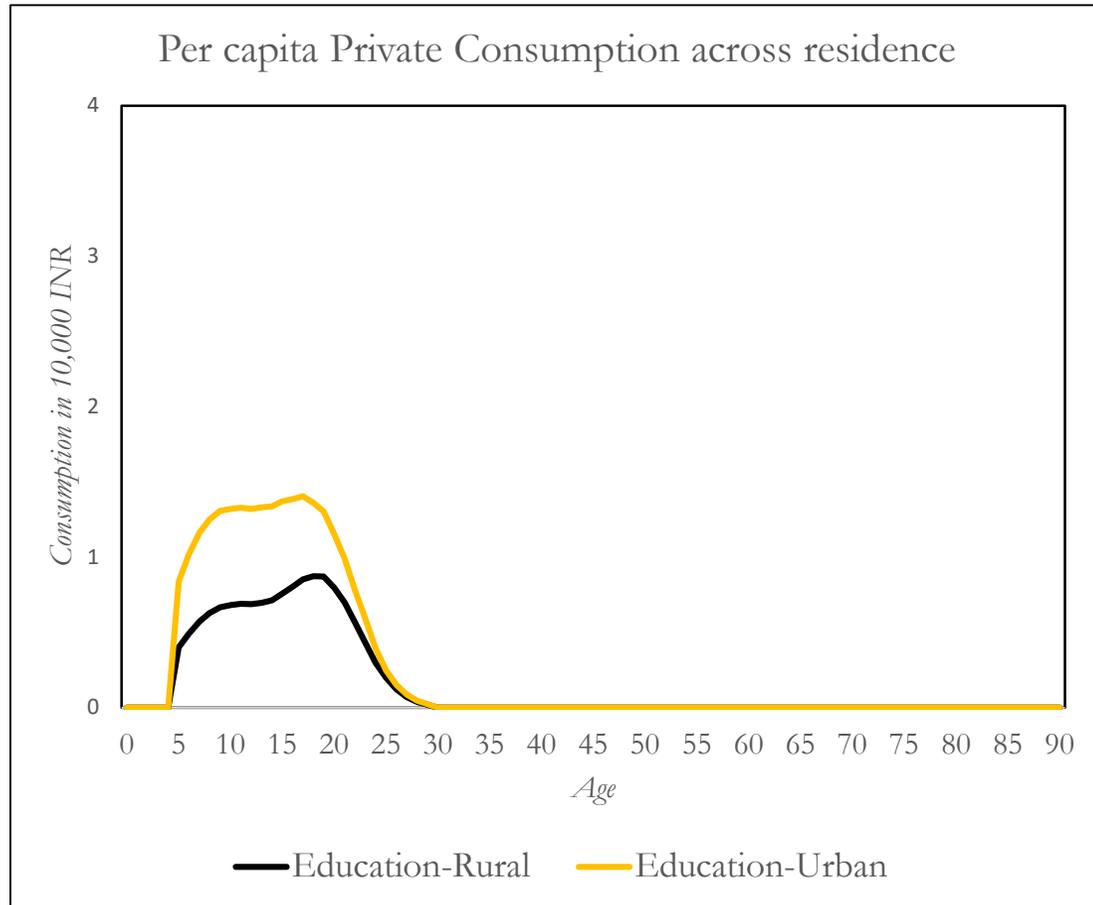

# Gender differential in health consumption

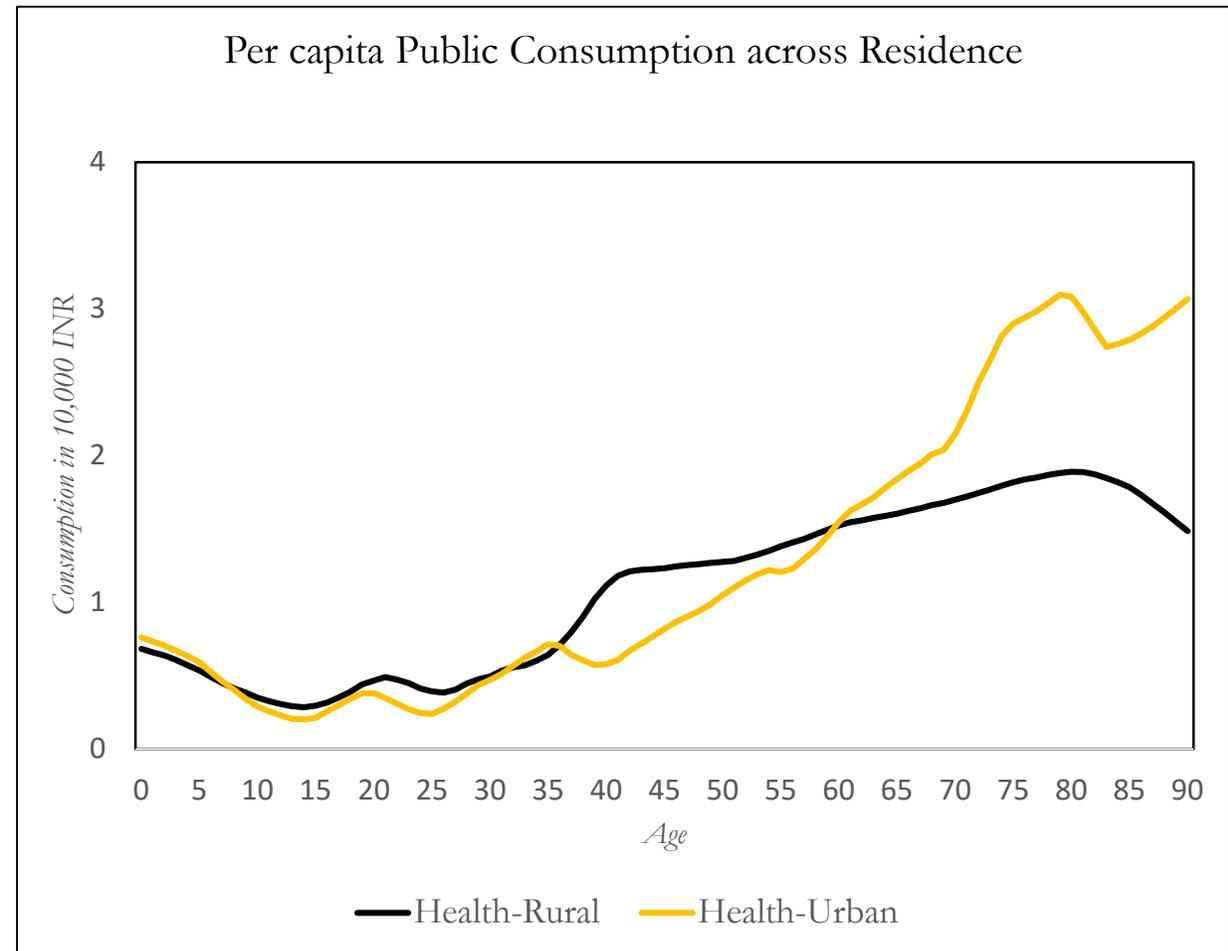

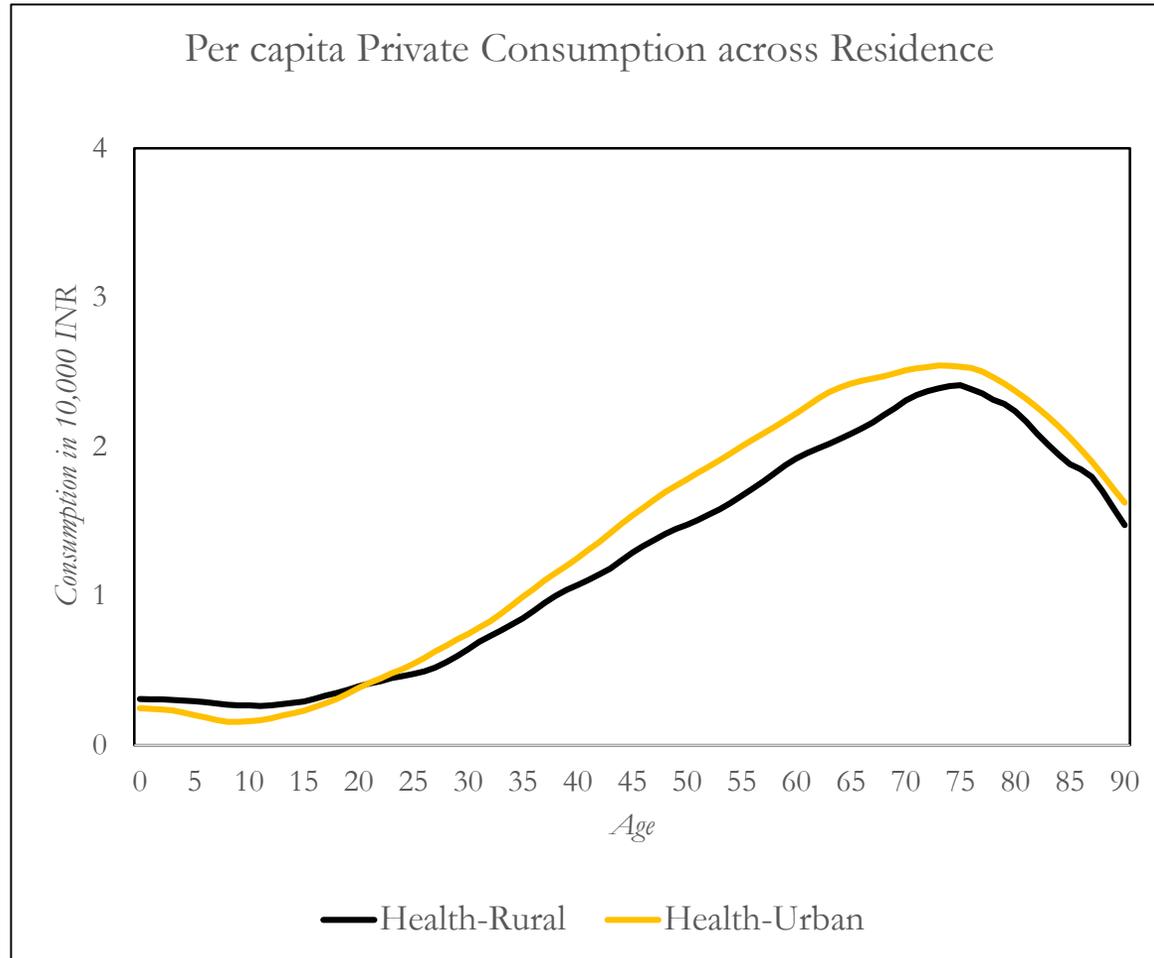

# Per capita labour income/consumption by urban/rural residence

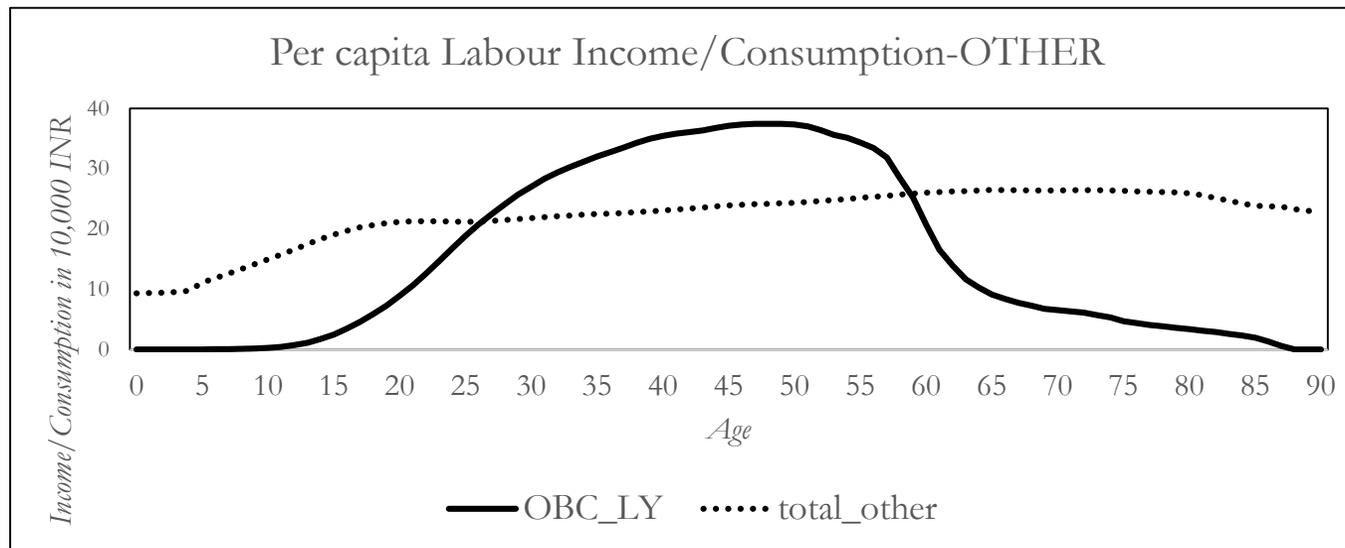

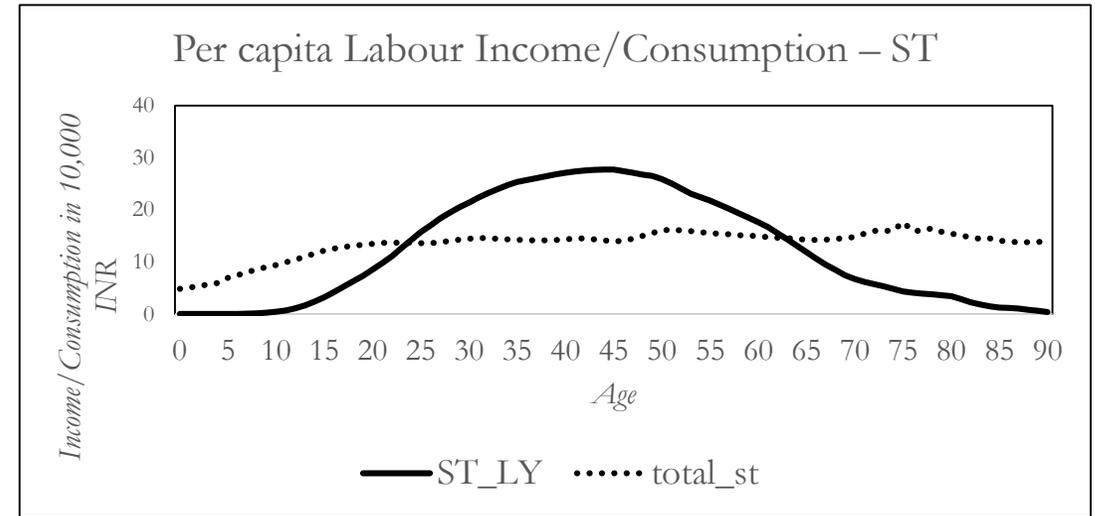

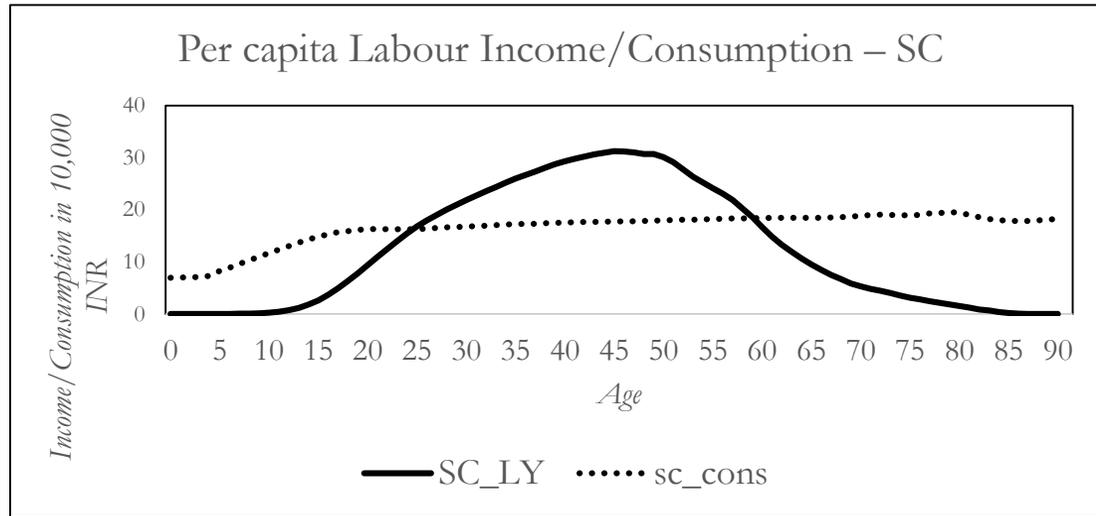

# Per capita education consumption by urban/rural residence

# Per capita health consumption across residence

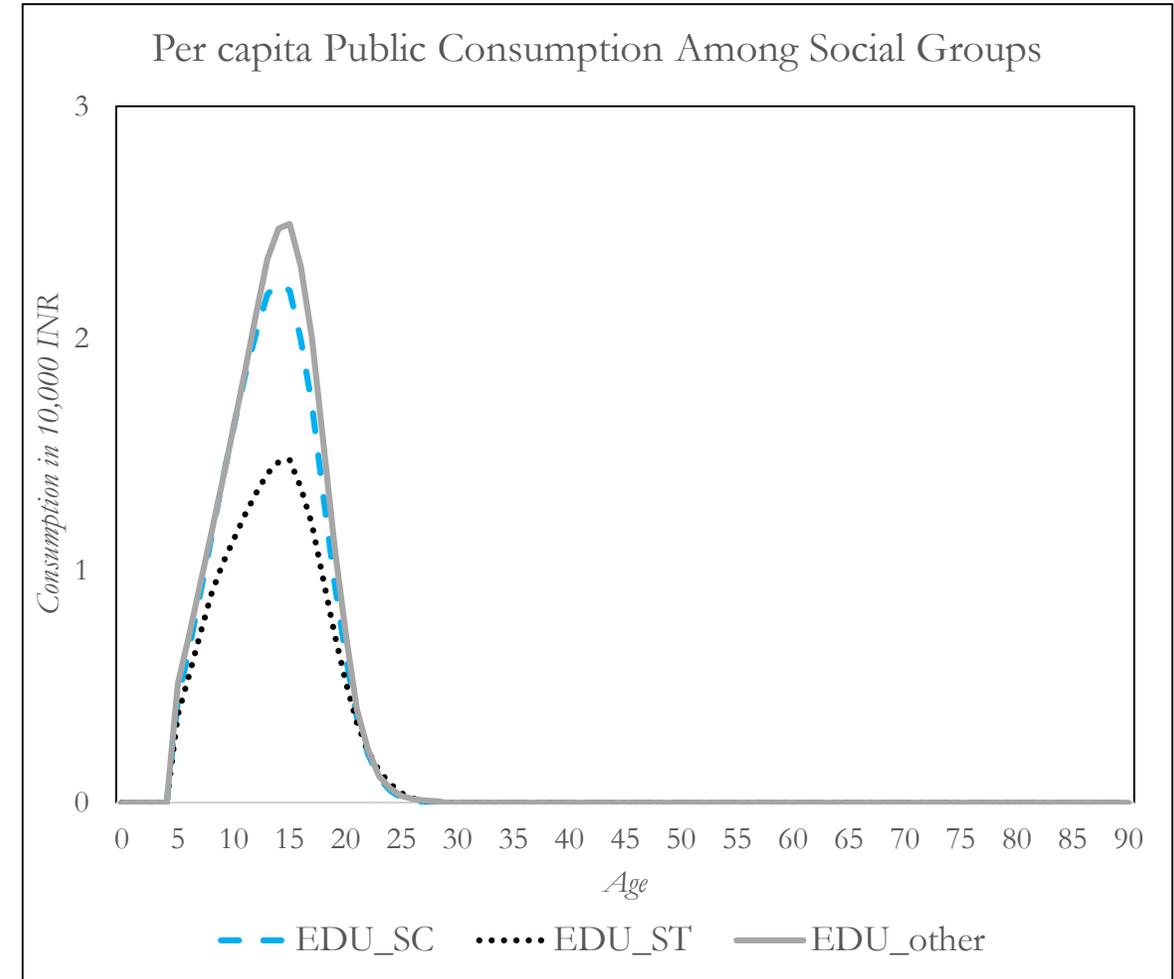

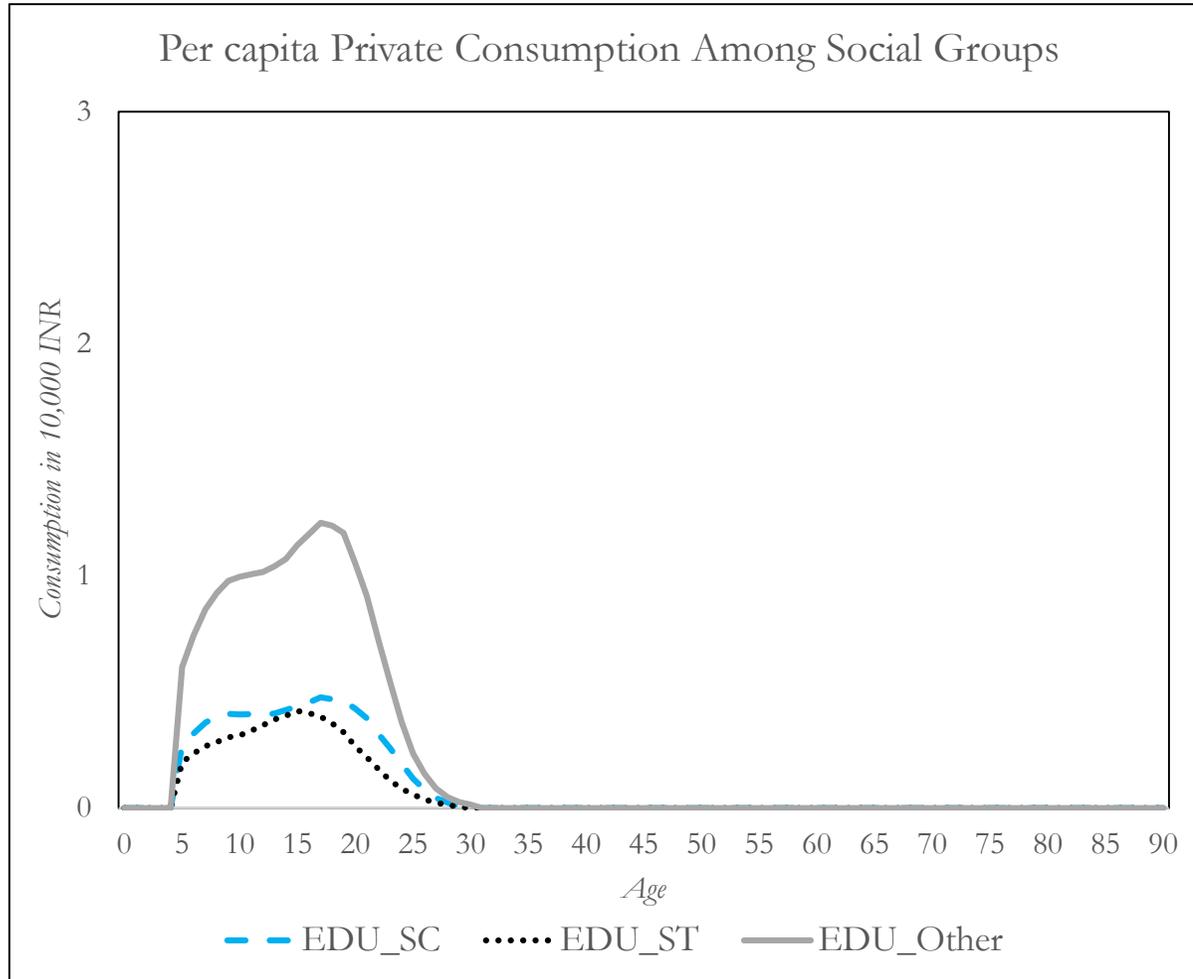

# Social group differential in labour income and consumption

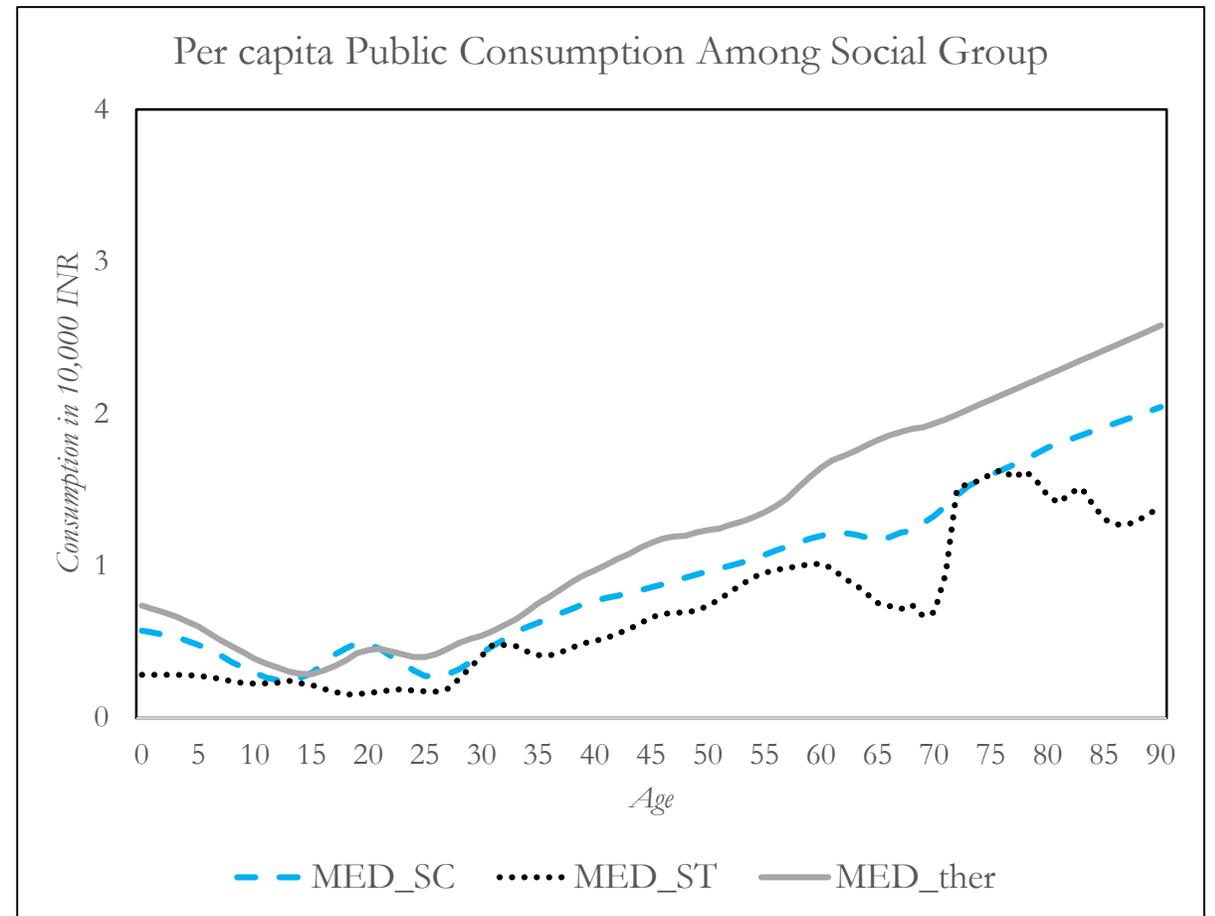

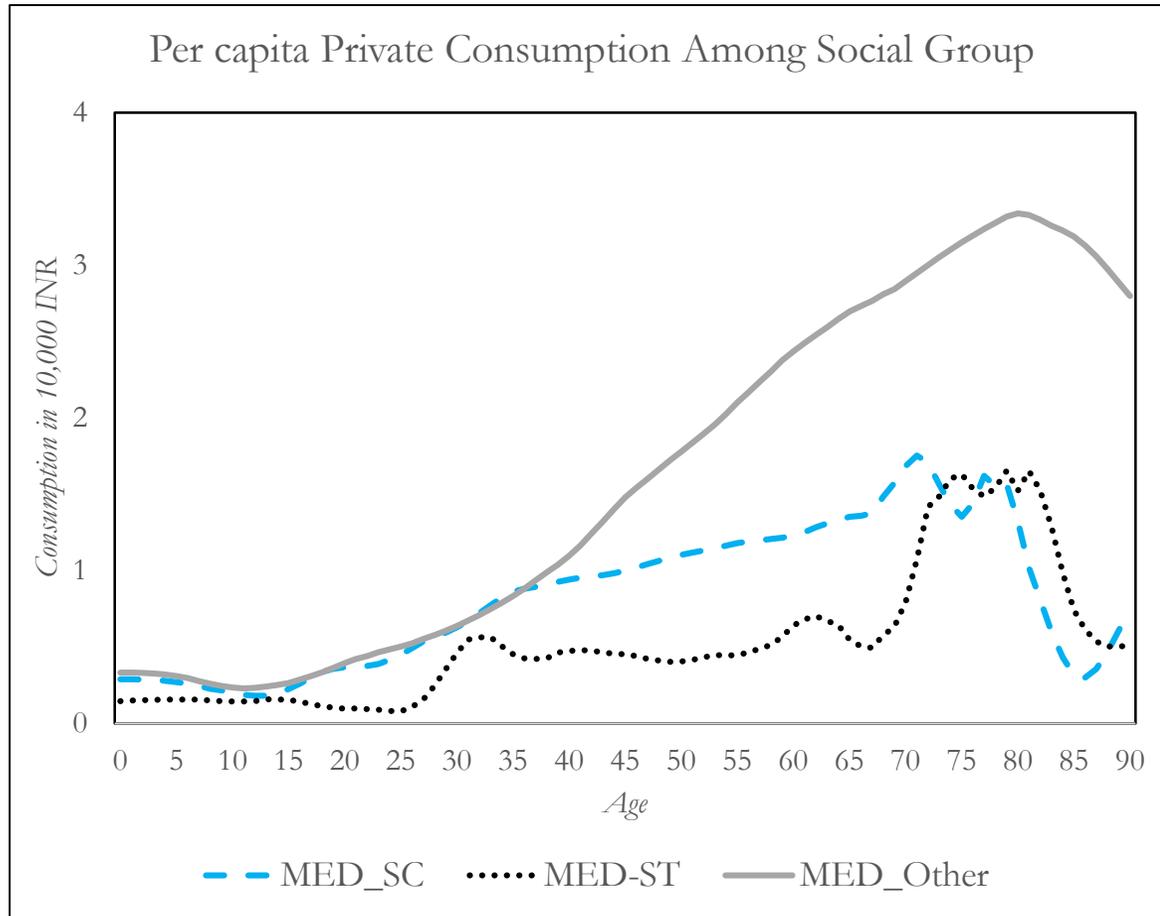

Officially designated groups of historically disadvantaged people in India

- Schedule Caste (SC)– 16.6%
- Schedule Tribe (ST) – 8.6%
- Other

# Per capita educational consumption

# Per capita health consumption

# Summary

---

- It is clear that inequality in terms of gender, residence and social group is very prominent in India.
- Overall public consumption of education and health care is higher than private consumption.
- Despite different kind of public programs, India is still far from a equal society.
